## CERTIFICATE

This certificate is issued in support of an application for Patent registration in a country outside New Zealand pursuant to the Patents Act 1953 and the Regulations thereunder.

I hereby certify that annexed is a true copy of the Provisional Specification as filed on 18 June 2003 with an application for Letters Patent number 526561 made by ANTHONY DAVID WOOLHOUSE.

I further certify that pursuant to a claim under Section 24(1) of the Patents Act 1953, a direction was given that the application proceed in the name of INDUSTRIAL RESEARCH LIMITED.

Dated 23 June 2004.

NEW ZEALAND PATENTS ACT 1953

PROVISIONAL SPECIFICATION

ZWITTERIONIC NON-LINEAR OPTOPHORES AND DEVICES  
INCORPORATING THESE

WE, ANTHONY DAVID WOOLHOUSE, a New Zealand citizen of 21 Harbour View Road, Northland, Wellington, New Zealand, and ANDREW JOHN KAY, a New Zealand citizen of 23 Moa Street, Alicetown, Lower Hutt, Wellington, New Zealand do hereby declare this invention to be described in the following statement:

## TECHNICAL FIELD

The present invention relates to a new class of second order non-linear optophores (optical chromophores) and processes for making them. The invention also relates to polymers containing the optical chromophores and devices incorporating the same.

## BACKGROUND OF THE INVENTION

In recent years there has been intense interest in molecules displaying large and efficient nonlinear optical responses ( $\mu\beta$ ) and in the electro-optic materials that permit the effective translation of these molecular properties into large, efficient and usable macroscopic responses. This interest is due to their potential application in emerging optoelectronic and photonic technologies.

Such materials contain molecules with highly polarisable electrons. The application of an electric field changes the electron polarisation, causing in an increase in the index of refraction. The resulting decrease in the velocity of light can be used to convert electric signals into optical signals.

In attempting to design all-plastic (i.e., all organic/polymeric) composite materials as active components of optoelectronic devices, a number of criteria need to be addressed. Ideally, the active molecules should display a large nonlinear optical response while still retaining synthetic expediency, transparency at communications wavelengths, and compatibility either when doped or functionalised within a polymer matrix. The composite materials must also exhibit thermal and photostability and maintain the noncentrosymmetry of the poled optophore array (i.e. temporal stability of the EO effect).

As these properties are interrelated, the structural features of a molecule that optimise one property may attenuate another. Accordingly, there continues to be a need for suitable optophores with improved properties.

Generally, optophores comprise donor (D) and acceptor (A) nuclei flanking a large, conjugated p-manifold which may contain auxilliary substituents to minimise potentially

deleterious aggregation effects that occur when the compounds are constrained within a matrix.

Conventional optophores are based upon 'left-hand-side' (LHS) systems (Marder-Perry plot) in which the ground-state electron distributions are dominated by only modest levels of charge separation or 'bond length alternation'. Such compounds are known to demonstrate positive solvatochromic behaviour ( $\mu\beta_0$ ) primarily as a result of the hyperpolarisability term  $\beta$ .

For example, US 6,067,186 describes compounds characterised as having tetherable N,N-dialkylanilino or N,N-dialkylaminothiopheno donor functionalities linked via a p-electron interconnect to heterocyclic systems that act as electron acceptors. Large pendant substituents may be placed on either or both the interconnect or the electron acceptor heterocycle.

In contrast, optophores whose ground states are predominated by 'zwitterionic' electron distributions ('right-hand-side' (RHS) optophores,) are expected to possess large ground-state dipole moments. This is considered to prevent efficient maximisation of macroscopic 'material' optical non-linearity as a result of unfavourable optophore dipole-dipole interactions during poling. As a result, those skilled in the art expect 'right-hand-side' optophores to be less useful in optoelectronic applications.

Surprisingly, it has been discovered that the zwitterionic non-linear optophores of the present invention achieve large molecular figures of merit ( $\mu\beta$ ) and are suitable for construction into polymer compositions which have application in optoelectronic and photonic technologies.

Accordingly, it is an object of the present invention to provide optophores with improved physical properties which also display a large and efficient nonlinear optical response or at least to provide the public with a useful choice.

## SUMMARY OF THE INVENTION

The present invention relates to a new class of zwitterionic non-linear optophores comprising a heteroaromatisable donor nucleus (D) connected to a cyanodicyanovinylidihydrofuran acceptor (A) via a substituted polyenic linker (L) and synthesis of same. The donor nuclei are selected from quinolinylidene (Q), pyridinylidene (PY) and benzothiazolidinylidene (BT) groups.

In one aspect the invention provides a compound of the general Formula I:

wherein:

D is selected from the group comprising

and

wherein:

R<sup>1</sup> is alkyl or hydroxyalkyl;

$R^2$  and  $R^3$  are H, or together form a 6-membered aromatic ring;

L is an optionally substituted conjugated polyenic chain of 3 to 7 carbon atoms; and

$R^4$  and  $R^5$  are independently alkyl, hydroxyalkyl or p-C<sub>6</sub>H<sub>4</sub>-OAc.

Preferably, L is an optionally substituted conjugated polyenic chain of 3 to 5 carbon atoms.

Optionally, substituents may be added to the chain so as to minimise optophore dipole-dipole interactions and/or to rigidify the linker. These substituents may form cyclic structures with the p-electron backbone of the linker group.

Preferably,  $R^1$  is hydroxyalkyl;

Preferably,  $R^2$  and  $R^3$  together form a 6-membered aromatic ring;

Preferably,  $R^4$  and  $R^5$  are independently alkyl or hydroxyalkyl.

Particularly preferred are compounds of the Q and PY series:

wherein

$R^1$  is  $\text{CH}_3$ ,  $\text{CH}_2\text{CH}_2\text{OH}$ ,  $\text{CH}_2\text{CH}(\text{OH})\text{CH}_2\text{OH}$ ;

$R^2$  and  $R^3$  are H, or together form a 6-membered aromatic ring;

One of  $R^4$  or  $R^5$  is hydroxyalkyl;

and L is an optionally substituted polyenic chain of 5 carbon atoms.

In particularly preferred compounds,  $R_1$  is dihydroxyalkyl. The provision of two hydroxyl groups allows the optophores of the invention to be used in the synthesis of new polyurethane, polycarbonate and polyamic acid/polyimide polymers.

The hydroxyalkyl group at  $R^4$  and/or  $R^5$  facilitates crosslinking of the polymers.

In another aspect the invention provides a method of preparing a compound of Formula I comprising:

(a) reacting a compound of Formula II:

wherein L is defined as above, with a compound of Formula III:

wherein  $R^4$  and  $R^5$  are as defined above, to form a compound of Formula IV:

(b) reacting the compound of Formula IV from step (a) with an azinium or azolium donor derivative of Formula V, VI, or VII, where X is halogen, to form a compound of Formula I.

Each of the above mentioned steps is described in greater detail below.

Preferably, step (a) is performed in acetic anhydride, however other solvents may be used such as methanol.

The (oligo)enamido dihydrofuran acceptor of Formula III is preferably reacted with an equimolar amount of a compound of Formula II. An equivalent of sodium acetate may also be added when a bisanil hydrochloride is used.

The donor derivatives IV, V and VI can be prepared using standard methods known in the art. Preferably, step (b) is performed by reacting stoichiometric quantities of each of the donor and acceptor components in refluxing acetic anhydride for 10 minutes. Preferably, the acetic anhydride contains an equivalent of triethylamine. Those skilled in the art will appreciate that other solvents and/or bases may be used in the method, and that the reaction time may differ depending on the nature of the reactants.

Substitution of the linker component can be achieved by modifying the bisanil component prior to reaction with the cyanodicyanovinylidihydrofuran acceptor of Formula III. For example, compounds wherein the linker comprises an alkylcycloalkenyl moiety (Formula VIII) can be accessed using the chlorocyclohexene dialdehyde bisanil of Formula IX,

Using this methodology, optophores of Formula I incorporating a variety of different linker structures can be accessed by utilising the correct bisanil derivative.

Compounds displaying  $\mu_{\text{calc}} \beta_{\text{O(HRS)}}$  values in excess of  $15\,000 \times 10^{-48}$  esu are considered to possess exceptional optical nonlinearity. The optophores of the present invention give  $\mu_{\text{calc}}$

$\beta_{o(HRS)}$  values of up to  $9384 \times 10^{-48}$  esu, therefore show great potential for use in optoelectronic applications.

In a further aspect the invention provides a composite material comprising

- (a) a compound of formula I; and
- (b) a polymer material

The polymer material can be a homopolymer or a co-polymer.

More preferably, the polymer material comprises polyurethane, polycarbonate, polyamic acid/ polyimide.

In a yet further aspect the invention provides an optoelectronic device comprising the composite material of the invention.

The devices may include single elements or arrays of phase and amplitude optical modulators formed from the composite materials of the invention.

The functions of such devices include, but are not limited to: electrical to optical signal transduction; radio wave to millimeter wave electromagnetic radiation (signal) detection; radio wave to millimeter wave electromagnetic generation (broadcasting); optical and millimeter wave beam steering; and signal processing such as analog to digital conversion, ultrafast switching of signals at nodes of optical networks, and highly precise phase control of optical and millimeter wave signals.

The composite materials of the invention can be fabricated into a wide range of optoelectronic devices using standard protocols known in the art. Many articles and patents describe suitable techniques.

The invention also provides a method of data transmission comprising transmitting light through a composite material of the invention.

Those skilled in the art will appreciate that various adaptations and modifications of the preferred embodiments can be configured without departing from the scope and spirit of the invention. Therefore, it is to be understood that the invention may be practices other than as specifically described herein.

## EXAMPLES

### General Information

$^1\text{H}$ - and  $^{13}\text{C}$  NMR spectra were recorded on a Bruker AVANCE 300MHZ spectrometer and proton multiplicities are defined by the usual notations. The assignments of resonances were made employing DEPT, COSY, HSQC and NOESY pulse sequences.

Uv-vis absorption spectra were recorded on a Hewlett-Packard 8452A diode array spectrophotometer and accurate mass measurements were made on a PE Biosystems Mariner mass spectrometer operating in the electrospray mode. Microanalyses were performed by the Campbell Microanalytical Laboratory, University of Otago, Dunedin, New Zealand and melting points are uncorrected.

The apparatus and experimental procedures for measuring hyper-Raleigh scattering (HRS) were exactly as described previously.  $\beta$  values were determined by using  $\beta_{800}$  for crystal violet chloride ( $338 \times 10^{-30}$  esu in methanol) as an external reference. All measurements were performed in DMSO and optical local field correction factors were applied.

### Uv-vis spectral characterisation

The electronic absorption spectra of the optophores from all PY, Q and BT series show intense charge-transfer absorption maxima in the 500 – 850 nm range and reveal the expected red shifts as the extent of conjugation is increased (Table 1). Significant windows of transparency exist in the 350-450 nm region of the spectrum. All compounds are negatively solvatochromic, a feature which qualitatively distinguishes these zwitterionic RHS systems from those 'belonging' to the LHS. The effect of benzannulation on  $\lambda_{\text{max}}$  of PY systems is quite pronounced, there being red shifts of up to 150 nm in going

from PY to Q, for example. The BT series shows not only the effects of benzannulation but also the effects of introducing a component of the p-interconnect which confers a degree of rigidity or configuration locking to the molecule. A compound containing the chlorocyclohexenylidene linkage is red-shifted by approximately 40 nm when compared to its iso-p-electronic series member containing a 7 carbon linker.

### Hyper Raleigh scattering studies

The first-order hyperpolarisabilities,  $\beta$ , of a representative suite of these zwitterionic optophores have been measured using the HRS technique with a femtosecond-pulsed fundamental of 800 nm and SH at 400 nm, at which wavelength no two-photon-induced fluorescence was detected by temporal resolution of emitted light signals. The  $\beta$  values are therefore true experimental values with no resonance enhancement. Furthermore, the resonance enhancement due to the fact that the CT band is in between the fundamental and the second harmonic indicates that the signs for the dynamic  $\beta$  at the measurement wavelength and for the static  $\beta_0$  are opposite, this being based upon assumptions applied to the two-state model.

HRS derived  $\beta$  and  $\beta_0$  values are presented in Table 2 together with calculated values of the ground-state dipole moment  $\mu$  and  $\beta_0$  and the corresponding figures of merit ( $\mu \beta_0$ ). In spite of the fact that 800 nm radiation triggered some (not unexpected) photodegradation of various of these optophores, the results clearly follow the expected trend which shows an increasing  $\beta$  as a function of increasing conjugation length. Interestingly, the effects of benzannulation upon the PY systems; that is, in going from PY to Q, have a marked effect upon the size of  $\beta_0$ . This is perhaps an indication of the increasing donor strength of Q systems over PY systems. To the extent that  $\beta_0$  values for the two BT compounds are reliable, then these data again suggest that the BT nucleus is midway in strength between the PY and Q donors, as some of our earlier findings had shown.

Inasmuch as comparisons of data acquired in different experimental regimes is meaningful, we note that the figures of merit ( $\mu_{\text{calc}} \beta_{0(\text{HRS})}$ ) we obtain for the longer PY and Q optophores (Table 2) are of the same order of magnitude as that reported for the optophores of US 6,067,186, members of which (LHS) class are characterised as having exceptional optical nonlinearities. The highest value of  $\mu_{\text{calc}} \beta_{0(\text{HRS})}$  reported for an optophore of US 6,067,186 is  $8255 \times 10^{-48}$  and those we obtain for the highest members of each of the PY and Q suites are  $8900 \times 10^{-48}$  and  $9384 \times 10^{-48}$  esu, respectively.

Table 2. Calculated and experimental values of  $\beta_o$  and  $\mu$ , and the corresponding figures of merit

| Compound    | $\mu^a$<br>(calc) | $\beta_o^b$<br>(calc) | $\beta_o^c$<br>(found) | $\mu_{(calc)}^2/\beta_{o(calc)}$ | $\mu_{(calc)}^2/\beta_{o(found)}$ |

#### 4-[-2-Anilinovinyl]-1-(2-hydroxyethyl)pyridinium iodide

A mixture of N-(2-hydroxyethyl)pyridinium iodide (24 g) and N,N'-diphenylformamidine (18 g) was stirred at 120 °C for 1 h. On cooling the mixture formed a dark tar. This was washed with 2 x 30 mL of ether and then allowed to stand, whereupon a brown-black solid formed. Recrystallisation from methanol afforded olive-green microcrystals (17.99 g; 54%), m.p. 192-193 °C. (Found: C; 48.94, H; 4.69 N; 7.94 C<sub>15</sub>H<sub>17</sub>N<sub>2</sub>O requires C; 48.93, H; 4.65, N; 7.61 %). <sup>1</sup>H NMR (d<sub>6</sub>-DMSO)  $\delta$  10.30 (s, 1H), 8.50 (d, *J* 13.0 Hz, 1H), 8.33 (d, *J* 7.1 Hz, 2H), 7.77 (d, *J* 6.8 Hz, 2H), 7.33 (m, 4H), 7.03 (m, 1H), 5.89 (d, *J* 13.0 Hz, 1H), 5.13 (t, *J* 5.10 Hz, 1H), 4.30 (t, *J* 4.9 Hz, 2H), 3.78 (m, 2H). <sup>13</sup>C NMR (d<sub>6</sub>-DMSO) 155.4

**Synthesis of (N-acetyl-N-phenyl-oligoenamino)-2(5H)-furanlydene}propanedinitrile acceptors: General Condensation Procedure.**

A mixture of the bisanil monohydrochloride (5.0 mmol), TCVDF(ref) (5.1 mmol) and anhydrous sodium acetate (5.1 mmol) in acetic anhydride was refluxed for 5 – 10 min before being allowed to cool and stand overnight. In the case of *N,N'*-diphenylformamidine free base, no sodium acetate was employed. Adducts were recovered by filtration as highly crystalline, coloured solids, and were washed with acetic anhydride (2x5 mL), followed by copious water and finally isopropanol. After drying in vacuum they were suitable for use without further purification.

**{4-(2-Acetanilidoethenyl)-3-cyano-5,5-dimethyl-2(5H)-furanlydene}propanedinitrile** was purified by recrystallisation from acetone and isolated as yellow plates (xx %), m.p. 274-278 °C (dec). (Found: C; 69.64, H; 4.57, N; 16.22. #### Synthesis of p-bridged pyridinylidene and quinolinylidene 2(5*H*)-furanylidene}propanedinitrile optophores (**7-15**): General Condensation Procedures.

**Method A:** Equimolar quantities of the appropriate N-methylazinium halide (**12a**, **15**, or **16**), the *oligoenamido* acceptor (XX-XX) and triethylamine were dissolved in acetic anhydride (10 ml/mmol) and the solution refluxed for 5-10 min before being allowed to cool slowly. Crystalline adducts were recovered by filtration and washed thoroughly with fresh acetic anhydride followed by copious quantities of water and then isopropanol and then dried. Yields were consistently in excess of 60 %.

**Method B:** As for Method A, but with methanol as the solvent instead of acetic anhydride. This method was used for reactions with the azinium halides **12b** or **14**.

**Method C:** Equimolar quantities of N-(2,3-dihydroxypropyl)-4-picolonium chloride (**B**) (ref) and the *oligoenamido* acceptor were treated with catalytic triethylamine in refluxing acetic anhydride as described above. The cooled reaction mixtures were poured into ether (c. 25 ml/mmol reagent) and stirred vigorously for several minutes. The liquors were decanted and the oily residues washed by stirring with further portions of ether. The residual insoluble oils were stirred vigorously with aqueous sodium hydroxide solution (2 % w/v, 25 ml/mmol) at 90 °C for 30 min and the resulting solids recovered by filtration and

washed with water (to neutrality) followed by isopropanol and then dried. Yields of the optophores recovered in this manner were again in excess of 55 %.

**(i) N-Methylpyridin-4(1*H*)-ylidene donors – Method A**
